Generative AI Use Disclosure

Nobel Prize API Analysis | DATA 607 | Nick

Tool and Session Details

Tool	Claude (Anthropic), accessed through the Claude app
Model	Claude Opus 5.5
Date of use	November 8, 2026, approximately 3:50 PM to 8:35 PM (Eastern)
Purpose	Learning how to use a REST API in R, debugging R code, and getting suggestions for analysis methods and visualizations

Summary of Use

I used Claude as a tutor and debugging assistant while I worked on this assignment. I asked it to explain API concepts in beginner terms, help me fix R errors, and suggest suitable visualizations and statistical tests. Claude did not have access to my data, my R session or my results. I ran all code myself and adapted it to my own dataset. The analysis choices, the results and their interpretation are my own.

Log of Interactions

#	My request	Assistance provided by Claude
1	How to use the Nobel Prize developer-zone API with R.	Looked up the API documentation; explained the endpoints, query parameters, JSON vs. CSV, and pagination; gave example code using jsonlite and httr2.
2	Asked for the explanation again in beginner terms, with jargon defined.	Explained the API, endpoint, query parameter, JSON, nesting, pagination and status codes using a restaurant-order analogy.
3	Shared my line *request("http://api.nobelprize.org/v1/prize.csv")*.	Explained that request() builds but does not send a request; showed req_perform() and reading the CSV; noted v1 vs. v2.1 and http vs. https.
4	Whether R has built-in API import or requires httr.	Explained that base R read.csv() reads URLs, that JSON needs jsonlite, and when httr2 is useful.
5	Joining country codes to full names across several code columns.	Showed repeated left_join() calls with renamed columns, and an across() lookup alternative.
6	How to combine two strings.	Explained paste(), paste0() and stringr::str_c(), including NA handling.
7	Shared a many-to-many join warning and a missing-column join error.	Diagnosed duplicate names (repeat winners) and a mismatched join column; suggested joining on id/year/category and using left_join for countries.
8	Matching country names that are not spelled identically.	Suggested the countrycode package, fuzzyjoin with caveats, and manual case_match() fixes.
9	Computing the difference in years between two date columns.	Showed lubridate interval()/time_length() and the issues with incomplete dates.
10	Computing an age from a year value that is not a date.	Showed make_date() (using the 10 December ceremony date) and plain year subtraction.
11	Age calculation returned a date, then values in the hundreds.	Diagnosed a Date-class year column created by as.Date() on numbers; showed how to recover the numeric year and exclude organizations.

#	My request	Assistance provided by Claude
12	Visualizing laureate movement from birth country to death country.	Suggested a network graph (igraph/ggraph) and a world flow map (sf/rnaturalearth), with example code.
13	A visual of countries vs. prize categories (Venn-style).	Recommended a heatmap and an UpSet plot instead of a 6-set Venn diagram; example code.
14	Putting percentages into the graph.	Gave a percentage heatmap (corrected so shares are calculated before filtering) and a 100% stacked bar alternative.
15	Average age at death by category and its relationship to field.	Suggested summary statistics, a box plot, ANOVA/Tukey/Kruskal-Wallis, and a regression controlling for birth year; pointed out survivorship bias.
16	Asked for one more analysis idea.	Suggested testing whether age at award has increased over time, by category.
17	Shared a 'cannot coerce type closure' error.	Explained that the year column no longer existed under that name, so R found the lubridate function.
18	Asked for a summary of the work as a PDF, and then for this disclosure.	Wrote a project summary PDF and this AI-use disclosure.
